my inclination is to not include in dose-response since we have other studies that analyzed more than one exposure category. What is your inclination? Does it add value?

Choi is the study with dermatitis; It adds another example of an allergy outcome - atopic dermatitis, that strengthens the eczema results. Mean age of this was 16 years, so borderline children/adult

No dose-response evaluation

found a 2009 and a 2011 study (that may be related) on allergy (atopic dermatitis) and atopic asthma and formaldehyde: case-control, Korea. Measured formaldehyde in homes, and compared distribution in cases and controls. Big difference for dermatitis, but not for asthma.

Ex. 5 Deliberative Process (DP)

Glinda

(a minor detail; I can't tell how long the sampling period was in the homes, but it's recent enough I should be able to get that info from the author)
